Importing and exporting data

R can read data in many different formats and it has several functions that can help us with that. The functions themselves have numerous parameters and options that can be used to read messy data correctly. I am not going to cover the ins and outs of that (it's rather tedious). If you're interested in learning more, I recommend the following article: https://www.datacamp.com/community/tutorials/r-data-import-tutorial.

My personal workflow to importing data is (1) clean the data using some spreadsheet software (Excel, Numbers, Google Sheets) and then (2) read the spreadsheet using the "Import Dataset" option in RStudio (top-right corner).

However, if the data are nicely formatted in *.csv or plain text format, using the functions read.csv and read.table is relatively painless.

For example, you can read depression.csv (hosted on my website) with the instruction

```
depression = read.csv("http://vicpena.github.io/sta9750/fall18/depression.csv")
```

If the dataset doesn't have column names, you only need to add header = FALSE. For example, suppose that we want to read in the following dataset: http://users.stat.ufl.edu/~winner/data/femrole.dat. It doesn't have variable names. We can read it in with

```
femrole = read.table("http://users.stat.ufl.edu/~winner/data/femrole.dat", header=F)
```

Exporting data with R is easy. If we want to export an existing data.frame to a *.csv file (which can be opened with Excel, Numbers, or any statistical package), we can use the function write.csv. For example, if we want to export the iris dataset into a file named iris.csv in the working directory:

```
data(iris)
write.csv(iris, file = "./iris.csv")
```

If you want the file to be saved somewhere else, you can change ./ by any path you want.

Another option is saving the workspace. That is, creating a file that has all the objects that we are currently working with (variables, data.frames, etc.). The function that allows us to do that is save. If we want to save all the variables and objects, we can simply type save(file='<path>/<filename>.RData'), where <path> is the path where the file will be saved and <filename> is the filename. We can also save only a subset of the variables. For example, suppose we want to save 2 objects named var1 and df. The command save(var1, df, file = '<path>/<filename>.RData') will do that for us.

Data subsetting

In this section, we'll cover how to subset variables and rows of datasets (mainly data.frames). We'll cover 2 different ways of filtering. We'll use the "traditional" way to do that (which doesn't require any extra libraries) and we'll use functions in library(dplyr) (which are faster in big datasets, cleaner, and more "intuitive").

Subsetting variables

We saw some of that in the previous chapter. Let's load the iris dataset.

```
data("iris")
str(iris)

## 'data.frame': 150 obs. of 5 variables:
## $ Sepal.Length: num 5.1 4.9 4.7 4.6 5 5.4 4.6 5 4.4 4.9 ...
```

```
## $ Sepal.Width : num 3.5 3 3.2 3.1 3.6 3.9 3.4 3.4 2.9 3.1 ...
## $ Petal.Length: num 1.4 1.4 1.3 1.5 1.4 1.7 1.4 1.5 1.4 1.5 ...
## $ Petal.Width : num 0.2 0.2 0.2 0.2 0.4 0.3 0.2 0.2 0.1 ...
## $ Species : Factor w/ 3 levels "setosa", "versicolor", ..: 1 1 1 1 1 1 1 1 1 1 1 ...
```

If we want to create a subset that contains, say, the first, the second, and the fifth columns, it's as easy as typing

```
sub1 = iris[,c(1,2,5)]
str(sub1)
```

```
## 'data.frame': 150 obs. of 3 variables:
## $ Sepal.Length: num 5.1 4.9 4.7 4.6 5 5.4 4.6 5 4.4 4.9 ...
## $ Sepal.Width : num 3.5 3 3.2 3.1 3.6 3.9 3.4 3.4 2.9 3.1 ...
## $ Species : Factor w/ 3 levels "setosa", "versicolor", ..: 1 1 1 1 1 1 1 1 1 1 ...
```

We can also create subsets by specifying which columns we want to remove. For example,

```
sub2 = iris[,-c(1,2,5)]
str(sub2)
```

```
## 'data.frame': 150 obs. of 2 variables:
## $ Petal.Length: num 1.4 1.4 1.3 1.5 1.4 1.7 1.4 1.5 1.4 1.5 ...
## $ Petal.Width : num 0.2 0.2 0.2 0.2 0.2 0.4 0.3 0.2 0.2 0.1 ...
```

contains all the columns in *except* the first, the second, and the fifth.

If we want to access specific columns of iris, we can use \$ followed by the name of the variable. For example, if we want to take a look at Species:

iris\$Species

```
##
     [1] setosa
                    setosa
                                setosa
                                            setosa
                                                       setosa
                                                                   setosa
     [7] setosa
                    setosa
                                setosa
                                            setosa
                                                       setosa
                                                                   setosa
##
    [13] setosa
                     setosa
                                setosa
                                            setosa
                                                                   setosa
                                                       setosa

## [145] virginica virginica virginica virginica virginica virginica
## Levels: setosa versicolor virginica
```

What we just covered is the traditional way of subsetting variables with R. With library(dplyr), we can use the command select. First, let's load the library (if you don't have it, you can install it with the command install.packages("dplyr").

```
library(dplyr)
```

The following command creates a subset that contains the first, the second, and the fifth variables,

```
sub3 = iris %>% select(1,2,5)
str(sub3)
```

```
## 'data.frame': 150 obs. of 3 variables:
## $ Sepal.Length: num 5.1 4.9 4.7 4.6 5 5.4 4.6 5 4.4 4.9 ...
## $ Sepal.Width : num 3.5 3 3.2 3.1 3.6 3.9 3.4 3.4 2.9 3.1 ...
## $ Species : Factor w/ 3 levels "setosa", "versicolor", ..: 1 1 1 1 1 1 1 1 1 1 1 ...
```

Note that there's a %>% separating iris and select. The operator %>% is what we call a "pipe". The commands in library(dplyr) (and library(tidyr), which we'll also cover) can be concatenated using the pipe operator. It ends up being pretty convenient. It looks odd at first, but you'll get used to it.

A nice feature of select is that we can easily select variables using their names:

```
sub4 = iris %>% select(Sepal.Length, Sepal.Width, Species)
head(sub4)
```

```
Sepal.Length Sepal.Width Species
##
## 1
              5.1
                          3.5 setosa
## 2
              4.9
                          3.0 setosa
## 3
              4.7
                           3.2 setosa
## 4
              4.6
                           3.1 setosa
## 5
              5.0
                           3.6 setosa
              5.4
                          3.9 setosa
## 6
```

As you can imagine, we can also create subsets by specifying which variables we want to exclude:

```
sub5 = iris %>% select(-c(1,2,5))
str(sub5)
```

```
## 'data.frame': 150 obs. of 2 variables:

## $ Petal.Length: num 1.4 1.4 1.3 1.5 1.4 1.7 1.4 1.5 1.4 1.5 ...

## $ Petal.Width : num 0.2 0.2 0.2 0.2 0.2 0.4 0.3 0.2 0.2 0.1 ...
```

```
sub6 = iris %>% select(-c(Sepal.Length, Sepal.Width, Species))
str(sub6)

## 'data.frame': 150 obs. of 2 variables:
## $ Petal.Length: num   1.4 1.4 1.3 1.5 1.4 1.7 1.4 1.5 1.4 1.5 ...
## $ Petal.Width : num   0.2 0.2 0.2 0.2 0.2 0.4 0.3 0.2 0.2 0.1 ...
```

Subsetting rows

\$ Species

We can subset rows by indicating which row numbers we want to keep (or exclude). For example, we can create a subset with the first, the thirtieth, and the fiftieth observations in the iris dataset as follows

```
sub1 = iris[c(1, 30, 50),]
str(sub1)
## 'data.frame':
                    3 obs. of 5 variables:
   $ Sepal.Length: num 5.1 4.7 5
## $ Sepal.Width : num 3.5 3.2 3.3
## $ Petal.Length: num 1.4 1.6 1.4
## $ Petal.Width : num 0.2 0.2 0.2
  $ Species
                  : Factor w/ 3 levels "setosa", "versicolor", ...: 1 1 1
And if we want to create a subset that includes all but the first, the thirtieth and the fiftieth observations:
sub2 = iris[-c(1, 30, 50),]
str(sub2)
                    147 obs. of 5 variables:
  $ Sepal.Length: num 4.9 4.7 4.6 5 5.4 4.6 5 4.4 4.9 5.4 ...
## $ Sepal.Width : num 3 3.2 3.1 3.6 3.9 3.4 3.4 2.9 3.1 3.7 ...
## $ Petal.Length: num 1.4 1.3 1.5 1.4 1.7 1.4 1.5 1.4 1.5 1.5 ...
   $ Petal.Width : num 0.2 0.2 0.2 0.2 0.4 0.3 0.2 0.2 0.1 0.2 ...
```

This is alright, but not very useful in practice. We're usually interested in subsets of rows that satisfy a certain condition. For example, we might be interested in creating a subset that only contains flowers of the setosa species. The following commands will do that for us

: Factor w/ 3 levels "setosa", "versicolor", ...: 1 1 1 1 1 1 1 1 1 1 ...

```
cond1 = (iris$Species == 'setosa')
str(cond1)
```

```
## logi [1:150] TRUE TRUE TRUE TRUE TRUE TRUE ...
sub3 = iris[cond1,]
str(sub3)
```

```
## 'data.frame': 50 obs. of 5 variables:
## $ Sepal.Length: num 5.1 4.9 4.7 4.6 5 5.4 4.6 5 4.4 4.9 ...
## $ Sepal.Width : num 3.5 3 3.2 3.1 3.6 3.9 3.4 3.4 2.9 3.1 ...
## $ Petal.Length: num 1.4 1.4 1.3 1.5 1.4 1.7 1.4 1.5 1.4 1.5 ...
## $ Petal.Width : num 0.2 0.2 0.2 0.2 0.2 0.4 0.3 0.2 0.2 0.1 ...
## $ Species : Factor w/ 3 levels "setosa", "versicolor", ..: 1 1 1 1 1 1 1 1 1 1 ...
```

In the first command, we create a logical type variable that takes on the value TRUE if Species is equal to setosa and FALSE otherwise (note that there are 2 equal signs between iris\$Species and setosa). In the second command, we use the logical variable to filter the iris dataset. We can use a similar strategy to create all sorts of subsets according to logical conditions. The operators are

- ==: equal to
- !=: not equal to
- >: greater than
- <: less than
- >=: greater or equal to
- <=: less than or equal to

For example, we can create a subset that contains only observations whose Sepal.Length is greater than 5

```
cond2 = (iris$Sepal.Length > 5)
sub4 = iris[cond2,]
```

And we can create a subset that contain all the observations whose Species isn't equal to setosa with

```
cond3 = iris$Species != 'setosa'
sub6 = iris[cond3,]
str(sub6)
```

```
## 'data.frame': 100 obs. of 5 variables:
## $ Sepal.Length: num 7 6.4 6.9 5.5 6.5 5.7 6.3 4.9 6.6 5.2 ...
## $ Sepal.Width : num 3.2 3.2 3.1 2.3 2.8 2.8 3.3 2.4 2.9 2.7 ...
## $ Petal.Length: num 4.7 4.5 4.9 4 4.6 4.5 4.7 3.3 4.6 3.9 ...
## $ Petal.Width : num 1.4 1.5 1.5 1.3 1.5 1.3 1.6 1 1.3 1.4 ...
## $ Species : Factor w/ 3 levels "setosa", "versicolor", ..: 2 2 2 2 2 2 2 2 2 2 ...
```

Logical conditions can be combined with "and", "or", and "not" operators, which in R are:

- & and
- |: or
- !: not

For example, we can create a subset that contains setosas whose Sepal.Length is greater than 5 with

```
cond4 = (iris$Species == 'setosa')&(iris$Sepal.Length > 5)
sub7 = iris[cond4,]
str(sub7)
```

```
## 'data.frame': 22 obs. of 5 variables:
## $ Sepal.Length: num 5.1 5.4 5.4 5.8 5.7 5.4 5.1 5.7 5.1 5.4 ...
## $ Sepal.Width : num 3.5 3.9 3.7 4 4.4 3.9 3.5 3.8 3.8 3.4 ...
## $ Petal.Length: num 1.4 1.7 1.5 1.2 1.5 1.3 1.4 1.7 1.5 1.7 ...
## $ Petal.Width : num 0.2 0.4 0.2 0.2 0.4 0.4 0.3 0.3 0.3 0.2 ...
## $ Species : Factor w/ 3 levels "setosa", "versicolor", ..: 1 1 1 1 1 1 1 1 1 1 1 ...
```

We can create a subset that contains observations that are not **setosas** or whose **Sepal.Width** is less than or equal to 4 with

```
cond5 = !(iris$Species == 'setosa')|(iris$Sepal.Width <= 4)
sub8 = iris[cond5,]
str(sub8)</pre>
```

```
## 'data.frame': 147 obs. of 5 variables:
## $ Sepal.Length: num 5.1 4.9 4.7 4.6 5 5.4 4.6 5 4.4 4.9 ...
## $ Sepal.Width : num 3.5 3 3.2 3.1 3.6 3.9 3.4 3.4 2.9 3.1 ...
## $ Petal.Length: num 1.4 1.4 1.3 1.5 1.4 1.7 1.4 1.5 1.4 1.5 ...
## $ Petal.Width : num 0.2 0.2 0.2 0.2 0.2 0.4 0.3 0.2 0.2 0.1 ...
```

```
## $ Species : Factor w/ 3 levels "setosa", "versicolor",..: 1 1 1 1 1 1 1 1 1 ...
```

We could've also written iris\$Species != 'setosa'.

What we just covered is the traditional way of subsetting rows with R. library(dplyr) has the function filter, which does the same thing with a cleaner syntax.

For example, we can create a subset that contains setosas whose Sepal.Length is greater than 5 as follows

```
sub1 = iris %>% filter(Species == 'setosa' & Sepal.Length > 5)
```

And we can create a subset that contains flowers whose Species isn't setosa or whose Sepal.Width is less than or equal to 4

```
sub2 = iris %>% filter(Species != 'setosa' | Sepal.Width <= 4)</pre>
```

As you can see, with filter we don't have to type in iris\$ whenever we want to specify a condition for variables in iris.

We can combine select and filter statements. For example, we can create a subset that excludes Species and only contains setosas as follows

```
sub3 = iris %>% filter(Species == 'setosa') %>% select(-Species)
str(sub3)
```

```
## 'data.frame': 50 obs. of 4 variables:
## $ Sepal.Length: num 5.1 4.9 4.7 4.6 5 5.4 4.6 5 4.4 4.9 ...
## $ Sepal.Width : num 3.5 3 3.2 3.1 3.6 3.9 3.4 3.4 2.9 3.1 ...
## $ Petal.Length: num 1.4 1.4 1.3 1.5 1.4 1.7 1.4 1.5 1.4 1.5 ...
## $ Petal.Width : num 0.2 0.2 0.2 0.2 0.2 0.4 0.3 0.2 0.2 0.1 ...
```

The order in which filter and select appear matters. If we typed the select statement first, we would get an error because when R tries to apply the filter, Species has already been excluded.

Tophat exercises

Read in the hsb2 dataset.

```
hsb2 = read.csv("http://vicpena.github.io/sta9750/spring19/hsb2.csv")
```

Answer the following questions:

- 1. What is the average 'math' score in the dataset?
- 2. What is the average 'math' score for those who scored 50 or greater in 'read'? Is it greater or smaller than the overall mean? Think about the result.
- 3. What is the average 'read' score in the dataset?
- 4. What is the average 'read' score for those who scored 50 or greater in 'math'? Is it greater or smaller than the overall mean? Compare your result to your answer in part 2.
- 5. What is the average difference in 'math' scores between individuals whose race is 'white' and those whose race is not 'white'?
- 6. Now, consider only those students whose 'ses' is 'high'. What is the average difference in 'math' scores between individuals whose race is 'white' and those whose race is not 'white'?
- 7. What is the percentage of individuals in the sample whose 'race' is 'white'?
- 8. What is the percentage of individuals of high 'ses' that are 'white'?
- 9. What percentage of students of low 'ses' went to 'public' schools?
- 10. What is the percentage of students with a 'math' score greater than 50 who went to 'public' schools?

Missing data

Sometimes, our datasets have missing values. In R, missing values are marked as NA.

For example, we can a vector with a missing value as follows

```
x = c(1:5, NA)
x
```

```
## [1] 1 2 3 4 5 NA
```

When we have missing values, we have to be careful. For example, if we try to take the average of x with mean:

```
mean(x)
```

```
## [1] NA
```

In general, arithmetic operations with NAs return NAs:

O+NA

```
## [1] NA
```

3*NA

```
## [1] NA
```

5/NA

```
## [1] NA
```

The function is.na can be used to filter missing values. For example,

```
cond = is.na(x)
cond
```

```
## [1] FALSE FALSE FALSE FALSE TRUE
```

```
x = x[!cond]
x
```

```
## [1] 1 2 3 4 5
```

For data.frames, the functions complete.cases and na.omit are useful.

Let's load the airquality dataset, which is built-in in 'R".

```
data(airquality)
```

The dataset has some air quality measurements that were taken in NYC from May to September in 1973 (see ?airquality for more details). The dataset has some missing values

```
summary(airquality)
```

```

```

There are 37 missing Ozone readings and 7 missing values in Solar.R. The function complete.cases, when applied to airquality, will create a logical vector whose values will be TRUE if the observation is "complete" (i.e., doesn't have any missing values) and FALSE if there is at least one variable with a missing value.

We can create a new dataset called aircomp that only contains complete observations as follows

```
aircomp = airquality[complete.cases(airquality),]
```

The command above is equivalent to

```
aircomp = na.omit(aircomp)
```

We are covering complete.cases because having a logical vector can help us identify the observations that have missing values. Indeed, we can filter the observations that are NOT complete cases, that is:

```
miss = airquality[!complete.cases(airquality),]
head(miss)
```

```

Sorting data

We can sort variables with the sort function. The default ordering is increasing. For example,

```
sort(iris$Sepal.Length)
```

sort(iris\$Species)

##	[1]	setosa	setosa	setosa	setosa	setosa	setosa
##	[7]	setosa	setosa	setosa	setosa	setosa	setosa
##	[13]	setosa	setosa	setosa	setosa	setosa	setosa
##	[19]	setosa	setosa	setosa	setosa	setosa	setosa
##	[25]	setosa	setosa	setosa	setosa	setosa	setosa
##	[31]	setosa	setosa	setosa	setosa	setosa	setosa
##	[37]	setosa	setosa	setosa	setosa	setosa	setosa

```
[43] setosa
                  setosa
                            setosa
                                       setosa
                                                 setosa

## Levels: setosa versicolor virginica
```

If we want descending order, we can add the option decreasing = TRUE:

```
sort(iris$Sepal.Length, decreasing = TRUE)
```

This only works with variables. What if we want to order a data.frame according to the values of one of the variables? For that task, we can use order.

For example, if we want to order iris in ascending order by Sepal.Length:

```
head(iris[order(iris$Sepal.Length),])
```

```
##
      Sepal.Length Sepal.Width Petal.Length Petal.Width Species
## 14
               4.3
                            3.0

```

When there are "ties", we can also sort the data by a second variable. For example, if we sort the data in descending order by Species, there will be a lot of observations that will share the same value of Species. If, given the species, we want to sort in ascending order by Petal.Width, this will do that for us

```
head(iris[order(-iris$Species, iris$Petal.Width),])
```

```
## Warning in Ops.factor(iris$Species): '-' not meaningful for factors

                                          5.6
```

An advantage of using arrange is that we don't have to type iris\$<variable name> all the time.

Type conversions

Oftentimes, categorical variables are coded as numerical. For example, let's look at the dataset femrole.dat, which is uploaded on Professor Winner's website. A description of the dataset can be found here and the data can be accessed here. As you can see, there are 4 categorical variables that are coded as numerical. How do we convert these variables to factors?

The following instruction reads in the data

```
femrole = read.table("http://users.stat.ufl.edu/~winner/data/femrole.dat", header = FALSE)
```

Now, we can print it

femrole

```
##

                   9
## 16
       2
          2
             2 2 33
```

First of all, the columns don't have interpretable names. We can change the names as follows:

```
colnames(femrole) = c("personality", "role", "friends", "dates", "count")
```

The variables personality, role, friends, and dates are categorical, but in femrole they are coded as numerical. To see this, we can run

```
str(femrole)
```

```
16 obs. of 5 variables:
  'data.frame':
   $ personality: int
                       1 1 2 2 1 1 2 2 1 1 ...
##
   $ role
                 : int
                        1 2 1 2 1 2 1 2 1 2 ...
##
   $ friends
                 : int
                        1 1 1 1 1 1 1 2 2 ...
##
                        1 1 1 1 2 2 2 2 1 1 ...
  $ dates
                 : int
   $ count
                       11 12 10 12 13 12 8 29 11 6 ...
                 : int
```

The output tells us that personality, role, friends, dates, and count are of type int, which means that they're coded as integers.

R functions can treat variables differently depending on whether they are numerical or categorical. If we don't convert the variables, we can get meaningless output.

We can convert the variables to factors using as.factor:

```
femrole$personality = as.factor(femrole$personality)
femrole$role = as.factor(femrole$role)
```

```
femrole$friends = as.factor(femrole$friends)
femrole$dates = as.factor(femrole$dates)
```

Let's run str again:

```
str(femrole)
```

```
## 'data.frame': 16 obs. of 5 variables:
## $ personality: Factor w/ 2 levels "1","2": 1 1 2 2 1 1 2 2 1 1 ...
## $ role : Factor w/ 2 levels "1","2": 1 2 1 2 1 2 1 2 1 2 ...
## $ friends : Factor w/ 2 levels "1","2": 1 1 1 1 1 1 1 1 2 2 ...
## $ dates : Factor w/ 2 levels "1","2": 1 1 1 1 2 2 2 2 2 1 1 ...
## $ count : int 11 12 10 12 13 12 8 29 11 6 ...
```

We have successfully changed their type from integer to factor. However, the levels of the factors are noninformative. We can change them using levels:

```
levels(femrole$personality) = c("Modern", "Traditional")
levels(femrole$role) = c("Modern", "Traditional")
levels(femrole$friends) = c("Low", "High")
levels(femrole$dates) = c("Low", "High")
```

TopHat Exercise Read in the dataset interfaith.dat, which is available on Professor Winner's website or by clicking here (the description is available here). Change the variable names to something informative, convert the appropriate variables into factors, and rename the levels of the factors using meaningful labels.

- What percentage of catholics are of low socioeconomic status?
- What percentage of protestants are of low socioeconomic status?
- What percentage of catholics are in an interfaith relationship?
- What percentage of protestants are in an interfaith relationship?

As you can imagine, other type conversions are possible. For instance, we can convert from matrix to data.frame with as.data.frame:

```
mat = matrix(c(1,2,3,4,5,6), nrow = 3, ncol = 3)
df = as.data.frame(mat)
```

Now, df is of class data.frame:

```
class(df)
```

```
## [1] "data.frame"
```

We can also convert data.frames that contain numeric variables to matrix using as.matrix.

```
df = data.frame(var1 = 1:3, var2 = 4:6)
mat = as.matrix(df)
```

And, unsurprisingly,

```
class(mat)
```

```
## [1] "matrix"
```

Reformatting datasets

Aggregated data

Let's take a closer look at the femrole dataset, which we formatted in a previous section.

femrole

```
##
                          role friends dates count
      personality

                                   High
                                         High
                                                  17
## 14
           Modern Traditional
                                   High
                                         High
                                                   8
## 15 Traditional
                        Modern
                                   High
                                         High
                                                   9
## 16 Traditional Traditional
                                                  33
                                   High High
```

The data are aggregated: each row corresponds to a certain social *profile*. The last column counts how many observations there are for each profile. Unfortunately, R isn't very good at working with data in this format. For example, suppose that we're interested in knowing how many women in the dataset have a High number of dates. If we type in

table(femrole\$dates)

```
## Low High ## 8 8
```

we get the wrong answer.

It's not only tables: plots and statistical methods in R are coded in a way that makes working with aggregated data difficult.

The most convenient format is a dataset where the rows correspond to different individuals (in this case, each row should correspond to a different woman). Thankfully, the function uncount in library(tidyr) makes the conversion easy.

```
unaggregated = femrole %>% uncount(count)
```

The argument of uncount is the variable that contains the counts (which, in this case, is conveniently named count). If you want to convert individual data to an aggregated format, you can use the function count.

We can convert unaggregated into an aggregated format as follows:

```
unaggregated %>% count(personality, role, friends, dates)
```

```
## # A tibble: 16 x 5
##
      personality role
                                friends dates
                                                    n
##
      <fct>
                   <fct>
                                <fct>
                                         <fct> <int>
    1 Modern
##
                   Modern
                                         Low
                                Low
                                                   11
    2 Modern
                   Modern
                                Low
                                         High
                                                   13
```

```

    7 Modern
                   Traditional High
                                        Low
                                                   6
                   Traditional High
                                                   8
##
    8 Modern
                                        High
    9 Traditional Modern
                                Low
                                        Low
                                                  10
## 10 Traditional Modern
                                Low
                                        High
                                                   8
## 11 Traditional Modern
                                High
                                        Low
                                                   4
                                                   9
## 12 Traditional Modern
                                High
                                        High
## 13 Traditional Traditional Low
                                        Low
                                                  12
                                                  29
## 14 Traditional Traditional Low
                                        High
## 15 Traditional Traditional High
                                                  13
                                        Low
                                                  33
## 16 Traditional Traditional High
                                        High
```

The arguments in count are the variables which we use for counting. For instance, compare the result above to

```
unaggregated %>% count(personality, dates)
```

```
## # A tibble: 4 x 3
## personality dates n
## <fct> <fct> <int>
## 1 Modern Low 40
## 2 Modern High 50
## 3 Traditional Low 39
## 4 Traditional High 79
```

TopHat Exercises Answer the following questions using the interfaith.dat dataset

- What is the percentage of low socioeconomic status individuals in an interfaith relationship?
- What is the percentage of high socioeconomic status individuals in an interfaith relationship?
- What is the value of (% men in interfaith relationship) (% women in interfaith relationship)?
- Let's consider protestants only. What is the value of (% men in interfaith relationship) (% women in interfaith relationship)?
- Let's consider catholics only. What is the value of (% men in interfaith relationship) (% women in interfaith relationship)?

gather: from wide format to long format

Suppose you want to compare outcomes with 3 treatments, and your data look like this

wide

```
## # A tibble: 5 x 3
##
     Treat1 Treat2 Treat3
##
      <dbl>
             <dbl>
                    <dbl>
## 1 -1.60
             0.983 - 0.2
     0.409 -0.671 -0.022
## 3 -0.019 -0.313 -1.74
## 4 -0.251
             3.25
## 5 0.306
            2.06
                   -0.083
```

Some people would say that the data is in "wide format."

Data in wide format aren't convenient for running our analyses: if you want to run statistical methods or create plots, most R functions expect to have all the outcomes in one column, and the categories (treatments) in another column. This alternative formatting is called "long format". You can go from wide to long format using gather in library(tidyr).

```
data %>% gather(key=treatment, value=outcome, Treat1, Treat2, Treat3)
```

```
## # A tibble: 15 x 2
##
      treatment outcome
##
                   <dbl>
      <chr>
##
    1 Treat1
                  -1.60
##
    2 Treat1
                   0.409
    3 Treat1
                  -0.019
    4 Treat1
                  -0.251
##
##
    5 Treat1
                   0.306
##
    6 Treat2
                   0.983
    7 Treat2
                  -0.671
##
    8 Treat2
                  -0.313
##
    9 Treat2
                   3.25
## 10 Treat2
                   2.06
## 11 Treat3
                  -0.2
## 12 Treat3
                  -0.022
## 13 Treat3
                  -1.74
## 14 Treat3
                   1.88
## 15 Treat3
                  -0.083
```

The first argument in gather is for naming the new column that contains the categories (the key), the second one is for naming the column where the new outcomes will be stored (the value), and then you write the names of the columns that contain the outcomes you want to gather. An equivalent way of writing the same thing is:

data %>% gather(key=treatment, value=outcome, Treat1:Treat3)

```
## # A tibble: 15 x 2
##
      treatment outcome
##
      <chr>
                   <dbl>
##
    1 Treat1
                  -1.60
##
    2 Treat1
                   0.409
    3 Treat1
                  -0.019
##
    4 Treat1
                  -0.251
##
    5 Treat1
                   0.306
##
    6 Treat2
                   0.983
##
    7 Treat2
                  -0.671
##
    8 Treat2
                  -0.313
##
    9 Treat2
                   3.25
## 10 Treat2
                   2.06
## 11 Treat3
                  -0.2
## 12 Treat3
                  -0.022
## 13 Treat3
                  -1.74
## 14 Treat3
                   1.88
## 15 Treat3
                  -0.083
```

In Treat1:Treat3 we gave R a range of columns which we want to gather (first to last). This is useful if you have many variables.

What if your data is in wide format, but you have an uneven number of observations? That is, your data looks something like this

```
uneven
## # A tibble: 5 x 3
##
     Treat1 Treat2 Treat3
##
      <dbl> <dbl>
                     <dbl>
## 1 -1.60
             0.983 -0.2
## 2
     0.409 -0.671
                    -0.022
## 3 -0.019 -0.313
                    -1.74
## 4 -0.251 3.25
                     NA
## 5 NA
             2.06
                     NA
Let's try to gather:
uneven %>% gather(key = treatment, value = outcome, Treat1:Treat3)
## # A tibble: 15 x 2
##
     treatment outcome
##
      <chr>
                 <dbl>
##
  1 Treat1
                -1.60
## 2 Treat1
                 0.409
## 3 Treat1
                -0.019
## 4 Treat1
                -0.251
## 5 Treat1
                NA
## 6 Treat2
                 0.983
## 7 Treat2
                -0.671
## 8 Treat2
                -0.313
## 9 Treat2
                 3.25
## 10 Treat2
                 2.06
## 11 Treat3
                -0.2
## 12 Treat3
                -0.022
## 13 Treat3
                -1.74
## 14 Treat3
                NA
## 15 Treat3
                NA
Unfortunately, we get some NAs. We can get rid of them with na.omit:
uneven %>% gather(key = treatment, value = outcome, Treat1:Treat3) %>%
          na.omit
## # A tibble: 12 x 2
##
     treatment outcome
##
      <chr>
                <dbl>
## 1 Treat1
                -1.60
## 2 Treat1
                 0.409
## 3 Treat1
                -0.019
## 4 Treat1
                -0.251
## 5 Treat2
                 0.983
## 6 Treat2
                -0.671
## 7 Treat2
                -0.313
## 8 Treat2
                 3.25
## 9 Treat2
                 2.06
## 10 Treat3
                -0.2
## 11 Treat3
                -0.022
## 12 Treat3
                -1.74
```

spread: from long to wide format

If you want to go from long to wide format, you can use spread.

For example, if your data are

data2

```
## # A tibble: 15 x 3
## # Groups:
               treatment [3]
##
      treatment outcome
                           ind
##
      <chr>
                  <dbl> <int>
##
    1 Treat1
                 -1.60
                             1
##
    2 Treat1

                  0.306
                             5
##
  6 Treat2
                  0.983
                             1
##
  7 Treat2
                 -0.671
                             2
  8 Treat2
                 -0.313
                             3
##
## 9 Treat2
                  3.25
                             4
## 10 Treat2
                  2.06
                             5
## 11 Treat3
                 -0.2
## 12 Treat3
                 -0.022
                             2
## 13 Treat3
                 -1.74
                             3
## 14 Treat3
                             4
                  1.88
## 15 Treat3
                 -0.083
                             5
```

You can convert it to wide format as follows

```
data2 %>% spread(treatment, outcome)
```

Note that data2 isn't just our dataset that came out of gathering. In fact, if we start with

```
gath = data %>% gather(key=treatment, value=outcome, Treat1:Treat3)
```

and we try to spread, we'll get an error. R complains because the rows of gath aren't uniquely identifiable. A way to get around that is creating index variables within the treatments

```
gath = gath %>% group_by(treatment) %>% mutate(id=row_number())
gath
```

```
## # A tibble: 15 x 3
## # Groups:
               treatment [3]
##
      treatment outcome
                            id
##
      <chr>
                  <dbl> <int>
##
    1 Treat1
                 -1.60
   2 Treat1
##
                  0.409
                             2
##
   3 Treat1
                 -0.019
                             3
                 -0.251
##
   4 Treat1
                             4
```

```
## 5 Treat1
                  0.306
##
  6 Treat2
                  0.983
                            1
                 -0.671
##
  7 Treat2
                            2
## 8 Treat2
                 -0.313
                            3
## 9 Treat2
                  3.25
                            4
## 10 Treat2
                  2.06
                            5
## 11 Treat3
                 -0.2
                            1
## 12 Treat3
                            2
                 -0.022
## 13 Treat3
                 -1.74
                            4
## 14 Treat3
                  1.88
## 15 Treat3
                 -0.083
                            5
```

and then, we can spread (and get rid of id):

```
gath %>% spread(treatment, outcome) %>% select(-id)
```

Creating and renaming variables

We can use mutate if we want to transform/create new variables. Let's load in the hsb2 dataset, and use it in our examples.

```
hsb2 = read.csv("http://vicpena.github.io/sta9750/spring19/hsb2.csv")
```

For example, if we want to create a new variable called avg which contains the average score in read, write, science, and socst:

```
hsb2 = hsb2 %>% mutate(avg=(read+write+science+socst)/4)
```

Or, equivalently (using "old" R):

```
hsb2\$avg = (hsb2\$read+hsb2\$write+hsb2\$science+hsb2\$socst)/4
```

We can also rename variables. If we want to change ses ro status:

```
hsb2 = hsb2 % rename(status = ses)
```

Obtaining summaries by categories of variables

We can create objects which contain summaries for different groups by combining group_by and summarize:

```
hsb2 %>% group_by(race) %>% summarize(medMath = median(math), sdMath = sd(math))
```

```
## 4 white 54 9.38
```

And we can combine these function with the other functions we learned today. For example:

```
hsb2 %>% group_by(race) %>% filter(math > 70) %>% summarize(n=n())
```

```
## # A tibble: 2 x 2
## race n
## <fct> <int>
## 1 asian 1
## 2 white 9
```

Tells us that there are 10 people who got a math score greater than 70, and that 1 of them is asian and 9 of them are white.
